5755

Introduction

This page shows how to perform a number of statistical tests using SPSS. Each section gives a brief description of the aim of the statistical test, when it is used, an example showing the SPSS commands and SPSS (often abbreviated) output with a brief interpretation of the output. You can see the page Choosing the Correct Statistical Test (https://stats.idre.ucla.edu/other/mult-pkg/whatstat/) for a table that shows an overview of when each test is appropriate to use. In deciding which test is appropriate to use, it is important to consider the type of variables that you have (i.e., whether your variables are categorical, ordinal or interval and whether they are normally distributed), see What is the difference between categorical, ordinal and interval variables? (https://stats.idre.ucla.edu/other/mult-pkg/whatstat/what-is-the-difference-between-categorical-ordinal-and-interval-variables/) for more information on this.

About the hsb data file

Most of the examples in this page will use a data file called **hsb2**, high school and beyond. This data file contains 200 observations from a sample of high school students with demographic information about the students, such as their gender (**female**), socio-economic status (**ses**) and ethnic background (**race**). It also contains a number of scores on standardized tests, including tests of reading (**read**), writing (**write**), mathematics (**math**) and social studies (**socst**). You can get the hsb data file by clicking on <u>hsb2</u> (https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav).

One sample t-test

A one sample t-test allows us to test whether a sample mean (of a normally distributed interval variable)

significantly differs from a hypothesized value. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to test whether the average writing score (write) differs significantly from 50. We can do this as shown below.

t-test

/testval = 50

/variable = write.

One-Sample Statistics

				Std. Error
	N	Mean	Std. Deviation	Mean
writing score	200	52.7750	9.47859	.67024

One-Sample Test

	Test Value = 50						
				Mean	95% Coi Interva Differ	l of the	
	t	df	Sig. (2-tailed)	Difference	Lower	Upper	
writing score	4.140	199	.000	2.7750	1.4533	4.0967	

The mean of the variable **write** for this particular sample of students is 52.775, which is statistically significantly different from the test value of 50. We would conclude that this group of students has a significantly higher mean on the writing test than 50.

One sample median test

hypothesized value. We will use the same variable, write, as we did in the <u>one sample t-test</u> (/spss/whatstat/#1sampt) example above, but we do not need to assume that it is interval and normally distributed (we only need to assume that write is an ordinal variable).

nptests

/onesample test (write) wilcoxon(testvalue = 50).

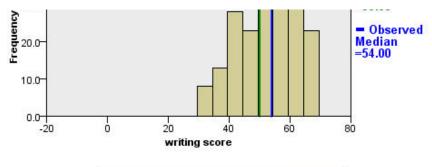

Hypothesis Test Summary

ii.	Null Hypothesis	Test	Sig.	Decision
1	The median of writing score equals 50.00.	One-Sample Wilcoxon Signed Rank Test	.000	Reject the null hypothesis.

Asymptotic significances are displayed. The significance level is .05.

One-Sample Wilcoxon Signed Rank Test

Total N	200
Test Statistic	13,177.000
Standard Error	806.235
Standardized Test Statistic	4.126
Asymptotic Sig. (2-sided test)	.000

Binomial test

categorical dependent variable significantly differs from a hypothesized value. For example, using the hsb2 data file (https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to test whether the proportion of females (female) differs significantly from 50%, i.e., from .5. We can do this as shown below.

npar tests

/binomial (.5) = female.

Binomial Test

		Category	N	Observed Prop.	Test Prop.	Asymp. Sig. (2-tailed)
FEMALE	Group 1	male	91	.46	.50	.229ª
	Group 2	female	109	.54		
	Total		200	1.00		

a. Based on Z Approximation.

The results indicate that there is no statistically significant difference (p = .229). In other words, the proportion of females in this sample does not significantly differ from the hypothesized value of 50%.

Chi-square goodness of fit

variable differ from hypothesized proportions. For example, let's suppose that we believe that the general population consists of 10% Hispanic, 10% Asian, 10% African American and 70% White folks. We want to test whether the observed proportions from our sample differ significantly from these hypothesized proportions.

npar test

/chisquare = race

/expected = 10 10 10 70.

RACE

	Observed N	Expected N	Residual
hispanic	24	20.0	4.0
asian	11	20.0	-9.0
african-amer	20	20.0	.0
white	145	140.0	5.0
Total	200		

Test Statistics

	RACE
Chi-Square a	5.029
df	3
Asymp, Sig.	.170

a. 0 cells (.0%) have expected frequencies less than

These results show that racial composition in our sample does not differ significantly from the hypothesized values that we supplied (chi-square with three degrees of freedom = 5.029, p = .170).

Two independent samples t-test

An independent samples t-test is used when you want to compare the means of a normally distributed

^{5.} The minimum expected cell frequency is 20.0.

interval dependent variable for two independent groups. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to test whether the mean for write is the same for males and females.

t-test groups = female(0 1) /variables = write.

Group Statistics

	female	N	Mean	Std. Deviation	Std. Error Mean
writing score	male	91	50.1209	10.30516	1.08027
	female	109	54.9908	8.13372	.77907

Independent Samples Test

Levene's Test for Equality of Variances			t-test for Equality of Means							
							Mean	Std. Error	95% Coi Interva Differ	lofthe
		F	Sig.	t	df	Sig. (2-tailed)	Difference	Difference	Lower	Upper
writing score	Equal variances assumed	11.133	.001	-3.734	198	.000	-4.8699	1.30419	-7.44183	-2.29806
	Equal variances not assumed			-3.656	169.707	.000	-4.8699	1.33189	-7.49916	-2.24073

Because the standard deviations for the two groups are similar (10.3 and 8.1), we will use the "equal variances assumed" test. The results indicate that there is a statistically significant difference between the mean writing score for males and females (t = -3.734, p = .000). In other words, females have a statistically significantly higher mean score on writing (54.99) than males (50.12).

• <u>SPSS Learning Module: An overview of statistical tests in SPSS (/spss/modules/an-overview-of-statistical-tests-in-spss/)</u>

Wilcoxon-Mann-Whitney test

be used when you do not assume that the dependent variable is a normally distributed interval variable (you only assume that the variable is at least ordinal). You will notice that the SPSS syntax for the Wilcoxon-Mann-Whitney test is almost identical to that of the independent samples t-test. We will use the same data file (the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav)) and the same variables in this example as we did in the independent t-test example ((/spss/whatstat/#2ittest) above and will not assume that write, our dependent variable, is normally distributed.

npar test

/m-w = write by female(0 1).

Test Statistics^a

	writing score
Mann-Whitney U	3606.000
Wilcoxon W	7792.000
Z	-3.329
Asymp. Sig. (2-tailed)	.001

a. Grouping Variable: FEMALE

The results suggest that there is a statistically significant difference between the underlying distributions of the write scores of males and the write scores of females (z = -3.329, p = 0.001).

See also

• FAQ: Why is the Mann-Whitney significant when the medians are equal?

(https://stats.idre.ucla.edu/other/mult-pkg/faq/general/faq-why-is-the-mann-whitney-significant-when-the-medians-are-equal/)

Chi-square test

variables. In SPSS, the **chisq** option is used on the **statistics** subcommand of the **crosstabs** command to obtain the test statistic and its associated p-value. Using the <u>hsb2 data file</u>

(https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), let's see if there is a relationship between the type of school attended (schtyp) and students' gender (female). Remember that the chisquare test assumes that the expected value for each cell is five or higher. This assumption is easily met in the examples below. However, if this assumption is not met in your data, please see the section on Fisher's exact test below.

crosstabs

/tables = schtyp by female
/statistic = chisq.

type of school * FEMALE Crosstabulation

Count

		FEM		
		male	female	Total
type of	public	77	91	168
school	private	14	18	32
Total		91	109	200

Chi-Square Tests

	Value	df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)	Exact Sig. (1-sided)
Pearson Chi-Square	.047b	1	.828		
Continuity Correction a	.001	1	.981		
Likelihood Ratio	.047	1	.828		
Fisher's Exact Test				.849	.492
Linear-by-Linear Association	.047	1	.829		
N of Valid Cases	200				

a. Computed only for a 2x2 table

These results indicate that there is no statistically significant relationship between the type of school attended and gender (chi-square with one degree of freedom = 0.047, p = 0.828).

Let's look at another example, this time looking at the linear relationship between gender (**female**) and socio-economic status (**ses**). The point of this example is that one (or both) variables may have more than two levels, and that the variables do not have to have the same number of levels. In this example,

female has two levels (male and female) and ses has three levels (low, medium and high).

crosstabs

/tables = female by ses

b. 0 cells (.0%) have expected count less than 5. The minimum expected count is 14.56.

/statistic = cnisq.

FEMALE * SES Crosstabulation

Count

			SES			
		low	middle	high	Total	
FEMALE	male	15	47	29	91	
	female	32	48	29	109	
Total		47	95	58	200	

Chi-Square Tests

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	4.577ª	2	.101
Likelihood Ratio	4.679	2	.096
Linear-by-Linear Association	3.110	1	.078
N of Valid Cases	200		

 ⁰ cells (.0%) have expected count less than 5. The minimum expected count is 21.39.

Again we find that there is no statistically significant relationship between the variables (chi-square with two degrees of freedom = 4.577, p = 0.101).

See also

• SPSS Learning Module: An Overview of Statistical Tests in SPSS (/spss/modules/an-overview-of-statistical-tests-in-spss/)

Fisher's exact test

The Fisher's exact test is used when you want to conduct a chi-square test but one or more of your cells has an expected frequency of five or less. Remember that the chi-square test assumes that each cell has an expected frequency of five or more, but the Fisher's exact test has no such assumption and can be used regardless of how small the expected frequency is. In SPSS unless you have the SPSS Exact Test Module, you can only perform a Fisher's exact test on a 2×2 table, and these results are presented by default. Please see the results from the chi squared example above.

One-way ANOVA

(with two or more categories) and a normally distributed interval dependent variable and you wish to test for differences in the means of the dependent variable broken down by the levels of the independent variable. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to test whether the mean of write differs between the three program types (prog). The command for this test would be:

oneway write by prog.

ANOVA

writing score

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	3175.698	2	1587.849	21.275	.000
Within Groups	14703.177	197	74.635		
Total	17878.875	199			

The mean of the dependent variable differs significantly among the levels of program type. However, we do not know if the difference is between only two of the levels or all three of the levels. (The F test for the **Model** is the same as the F test for **prog** because **prog** was the only variable entered into the model. If other variables had also been entered, the F test for the **Model** would have been different from **prog**.) To see the mean of **write** for each level of program type,

means tables = write by prog.

Report

writing score

type of program	Mean	Z	Std. Deviation
general	51.3333	45	9.39778
academic	56.2571	105	7.94334
vocation	46.7600	50	9.31875
Total	52.7750	200	9.47859

From this we can see that the students in the academic program have the highest mean writing score, while students in the vocational program have the lowest.

in-spss/) • SPSS Library: Understanding and Interpreting Parameter Estimates in Regression and ANOVA (/spss/library/spss-libraryunderstanding-and-interpreting-parameter-estimates-in-regressionand-anova/) Kruskal Wallis test

ordinal dependent variable. In other words, it is the non-parametric version of ANOVA and a generalized form of the Mann-Whitney test method since it permits two or more groups. We will use the same data file as the one way ANOVA example (/spss/whatstat/#1anova) above (the hsb2 data file (https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav)) and the same variables as in the example above, but we will not assume that write is a normally distributed interval variable.

npar tests

/k-w = write by prog (1,3).

Ranks

	type of program	N	Mean Rank
writing score	general	45	90.64
	academic	105	121.56
	vocation	50	65.14
	Total	200	

Test Statisticsa,b

	writing score
Chi-Square	34.045
df	2
Asymp, Sig.	.000

a. Kruskal Wallis Test

b. Grouping Variable: type of program

If some of the scores receive tied ranks, then a correction factor is used, yielding a slightly different value of chi-squared. With or without ties, the results indicate that there is a statistically significant difference among the three type of programs.

Paired t-test

subject) and you want to see if the means on these two normally distributed interval variables differ from one another. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav) we will test whether the mean of read is equal to the mean of write.

t-test pairs = read with write (paired).

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair	reading score	52.2300	200	10.25294	.72499
1	writing score	52.7750	200	9.47859	.67024

Paired Samples Test

		Paired Differences							
					95% Coi Interva	ofthe			
1				Std. Error	Differ	ence			
		Mean	Std. Deviation	Mean	Lower	Upper	t	df	Sig. (2-tailed)
Pair 1	reading score - writing score	5450	8.88667	.62838	-1.7841	.6941	867	199	.387

These results indicate that the mean of **read** is not statistically significantly different from the mean of **write** (t = -0.867, p = 0.387).

Wilcoxon signed rank sum test

Wilcoxon signed rank sum test when you do not wish to assume that the difference between the two variables is interval and normally distributed (but you do assume the difference is ordinal). We will use the same example as above, but we will not assume that the difference between **read** and **write** is interval and normally distributed.

npar test

/wilcoxon = write with read (paired).

Ranks

		N	Mean Rank	Sum of Ranks
reading score -	Negative Ranks	97ª	95.47	9261.00
writing score	Positive Ranks	88p	90.27	7944.00
	Ties	15°		
	Total	200		

- a. reading score < writing score
- b. reading score > writing score
- c. writing score = reading score

Test Statistics^b

	reading score - writing score
Z	903ª
Asymp. Sig. (2-tailed)	.366

- a. Based on positive ranks.
- b. Wilcoxon Signed Ranks Test

The results suggest that there is not a statistically significant difference between read and write.

If you believe the differences between **read** and **write** were not ordinal but could merely be classified as positive and negative, then you may want to consider a sign test in lieu of sign rank test. Again, we will use the same variables in this example and assume that this difference is not ordinal.

npar test

/sign = read with write (paired).

Frequencies

		Ν
writing score -	Negative Differencesa	88

	1.00	18	26	44
Total		153	47	200

Chi-Square Tests

	Value	Exact Sig. (2-sided)
McNemar Test		.749ª
N of Valid Cases	200	

a. Binomial distribution used.

McNemar's chi-square statistic suggests that there is not a statistically significant difference in the proportion of students in the **himath** group and the proportion of students in the **hiread** group.

One-way repeated measures ANOVA

independent variable and a normally distributed interval dependent variable that was repeated at least twice for each subject. This is the equivalent of the paired samples t-test, but allows for two or more levels of the categorical variable. This tests whether the mean of the dependent variable differs by the categorical variable. We have an example data set called rb4wide (https://stats.idre.ucla.edu/wp-content/uploads/2016/02/rb4wide.sav), which is used in Kirk's book Experimental Design. In this data set, **y** is the dependent variable, **a** is the repeated measure and **s** is the variable that indicates the subject number.

You will notice that this

output gives four different p-values. The output labeled "sphericity assumed" is the p-value (0.000) that you would get if you assumed compound symmetry in the variance-covariance matrix. Because that assumption is often not valid, the three other p-values offer various corrections (the Huynh-Feldt, H-F, Greenhouse-Geisser, G-G and Lower-bound). No matter which p-value you use, our results indicate that we have a statistically significant effect of **a** at the .05 level.

Repeated measures logistic regression

regression that accounts for the effect of multiple measures from single subjects, you can perform a repeated measures logistic regression. In SPSS, this can be done using the **GENLIN** command and indicating binomial as the probability distribution and logit as the link function to be used in the model. The <u>exercise data file (https://stats.idre.ucla.edu/wp-content/uploads/2016/02/exercise.sav)</u> contains 3 pulse measurements from each of 30 people assigned to 2 different diet regiments and 3 different exercise regiments. If we define a "high" pulse as being over 100, we can then predict the probability of a high pulse using diet regiment.

GET FILE='C:mydatahttps://stats.idre.ucla.edu/wp-content/uploads/2016/02/exercise.sav'.

GENLIN highpulse (REFERENCE=LAST)

Friedman test

You perform a Friedman test when you have one within-subjects independent variable with two or more levels and a dependent variable that is not interval and normally distributed (but at least ordinal). We will use this test to determine if there is a difference in the reading, writing and math scores. The null hypothesis in this test is that the distribution of the ranks of each type of score (i.e., reading, writing and math) are the same. To conduct a Friedman test, the data need to be in a long format. SPSS handles this for you, but in other statistical packages you will have to reshape the data before you can conduct this test.

npar tests

/friedman = read write math.

Ranks

	Mean Rank
reading score	1.96
writing score	2.04
math score	2.01

Test Statistics

N	200
Chi-Square	.645
df	2
Asymp, Sig.	.724

a. Friedman Test

Friedman's chi-square has a value of 0.645 and a p-value of 0.724 and is not statistically significant. Hence, there is no evidence that the distributions of the three types of scores are different.

Ordered logistic regression

example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav) we will create an ordered variable called <a href="write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write-write

Test of Parallel Lines^a

Model	-2 Log Likelihood	Chi-Square	df	Sig.
Null Hypothesis	252.151			
General	250.104	2.047	3	.563

The null hypothesis states that the location parameters (slope coefficients) are the same across response categories.

a. Link function: Logit.

The results indicate that the overall model is statistically significant (p < .000), as are each of the predictor variables (p < .000). There are two thresholds for this model because there are three levels of the outcome variable. We also see that the test of the proportional odds assumption is non-significant (p = .563). One of the assumptions underlying ordinal logistic (and ordinal probit) regression is that the

relationship between each pair of outcome groups is the same. In other words, ordinal logistic regression assumes that the coefficients that describe the relationship between, say, the lowest versus all higher categories of the response variable are the same as those that describe the relationship between the next lowest category and all higher categories, etc. This is called the proportional odds assumption or the parallel regression assumption. Because the relationship between all pairs of groups is the same, there is only one set of coefficients (only one model). If this was not the case, we would need different models (such as a generalized ordered logit model) to describe the relationship between each pair of outcome groups.

Factorial logistic regression

a dichotomous dependent variable. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav) we will use **female** as our dependent variable, because it is the only dichotomous variable in our data set; certainly not because it common practice to use gender as an outcome variable. We will use type of program (**prog**) and school type (**schtyp**) as our predictor variables. Because **prog** is a categorical variable (it has three levels), we need to create dummy codes for it. SPSS will do this for you by making dummy codes for all variables listed after the keyword **with**. SPSS will also create the interaction term; simply list the two variables that will make up the interaction separated by the keyword **by**.

logistic regression female with prog schtyp prog by schtyp
/contrast(prog) = indicator(1).

Dependent Variable Encoding

Correlation

A correlation is useful when you want to see the relationship between two (or more) normally distributed

interval variables. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav) we can run a correlation between two continuous variables, read and write.

correlations

/variables = read write.

Correlations

		reading score	writing score
reading score	Pearson Correlation	1	.597
	Sig. (2-tailed)		.000
	N	200	200
writing score	Pearson Correlation	.597	1
	Sig. (2-tailed)	.000	
	N	200	200

In the second example, we will run a correlation between a dichotomous variable, **female**, and a continuous variable, **write**. Although it is assumed that the variables are interval and normally distributed, we can include dummy variables when performing correlations.

correlations

/variables = female write.

Correlations

		FEMALE	writing score
FEMALE	Pearson Correlation	1	.256
	Sig. (2-tailed)		.000
	N	200	200
writing score	Pearson Correlation	.256	1
	Sig. (2-tailed)	.000	
	N	200	200

In the first example above, we see that the correlation between **read** and **write** is 0.597. By squaring the correlation and then multiplying by 100, you can determine what percentage of the variability is shared. Let's round 0.597 to be 0.6, which when squared would be .36, multiplied by 100 would be 36%. Hence **read** shares about 36% of its variability with **write**. In the output for the second example, we can see the correlation between **write** and **female** is 0.256. Squaring this number yields .065536, meaning that **female** shares approximately 6.5% of its variability with **write**.

Simple linear regression

interval predictor and one normally distributed interval outcome variable. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to look at the relationship between writing scores (write) and reading scores (read); in other words, predicting write from read.

regression variables = write read
/dependent = write
/method = enter.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.597ª	.356	.353	7.62487

a. Predictors: (Constant), reading score

ANOVA

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	6367.421	1	6367.421	109.521	.000ª
	Residual	11511.454	198	58.139		
1	Total	17878.875	199			

a. Predictors: (Constant), reading score

Coefficients^a

		Unstandardized Coefficients		Standardi zed Coefficien ts		
Model		В	Std. Error	Beta	t	Sig.
1	(Constant)	23.959	2.806		8.539	.000
	reading score	.552	.053	.597	10.465	.000

a. Dependent Variable: writing score

We see that the relationship between **write** and **read** is positive (.552) and based on the t-value (10.47) and p-value (0.000), we would conclude this relationship is statistically significant. Hence, we would say there is a statistically significant positive linear relationship between reading and writing.

Non-parametric correlation

distributed and interval (but are assumed to be ordinal). The values of the variables are converted in ranks and then correlated. In our example, we will look for a relationship between **read** and **write**. We will not assume that both of these variables are normal and interval.

nonpar corr

/variables = read write

/print = spearman.

Correlations

			reading score	writing score
Spearman's rho	reading score	Correlation Coefficient	1.000	.617
		Sig. (2-tailed)		.000
		N	200	200
	writing score	Correlation Coefficient	.617	1.000
		Sig. (2-tailed)	.000	
		N	200	200

The results suggest that the relationship between **read** and **write** (rho = 0.617, p = 0.000) is statistically significant.

Simple logistic regression

one variable in the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav)
that is coded 0 and 1, and that is **female**. We understand that **female** is a silly outcome variable (it would make more sense to use it as a predictor variable), but we can use **female** as the outcome variable to illustrate how the code for this command is structured and how to interpret the output. The first variable listed after the **logistic** command is the outcome (or dependent) variable, and all of the rest of the variables are predictor (or independent) variables. In our example, **female** will be the outcome variable, and **read** will be the predictor variable. As with OLS regression, the predictor variables must be either dichotomous or continuous; they cannot be categorical.

logistic regression female with read.

Dependent Variable Encoding

Original Value	Internal Value
male	0
female	1

Omnibus Tests of Model Coefficients

		Chi-square	df	Sig.

vocation	844	-6.58E-02		

Unstandardized canonical discriminant functions evaluated at group means

Clearly, the SPSS output for this procedure is quite lengthy, and it is beyond the scope of this page to explain all of it. However, the main point is that two canonical variables are identified by the analysis, the first of which seems to be more related to program type than the second.

One-way MANOVA

variables. In a one-way MANOVA, there is one categorical independent variable and two or more dependent variables. For example, using the https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), say we wish to examine the differences in read, write and math broken down by program type (prog).

glm read write math by prog.

a. R Squared = .594 (Adjusted R Squared = .586)

These results show that all of the variables in the model have a statistically significant relationship with the joint distribution of **write** and **read**.

Canonical correlation

b. R Squared = .584 (Adjusted R Squared = .576)

of variables. For each set of variables, it creates latent variables and looks at the relationships among the latent variables. It assumes that all variables in the model are interval and normally distributed. SPSS requires that each of the two groups of variables be separated by the keyword with. There need not be an equal number of variables in the two groups (before and after the with).

The output above shows the linear combinations corresponding to the first canonical correlation. At the bottom of the output are the two canonical correlations. These results indicate that the first canonical correlation is .7728. The F-test in this output tests the hypothesis that the first canonical correlation is equal to zero. Clearly, F = 56.4706 is statistically significant. However, the second canonical correlation of .0235 is not statistically significantly different from zero (F = 0.1087, P = 0.7420).

Factor analysis

(https://stats.idre.ucla.edu/wp-content/uploads/2016/02/hsb2-3.sav), let's suppose that we think that there are some common factors underlying the various test scores. We will include subcommands for varimax rotation and a plot of the eigenvalues. We will use a principal components extraction and will retain two factors. (Using these options will make our results compatible with those from SAS and Stata and are not necessarily the options that you will want to use.)

social studies score	.222	.922

Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.

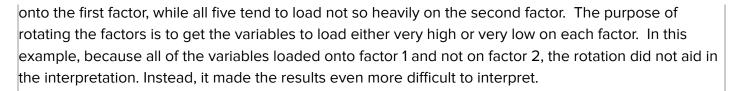

a. Rotation converged in 3 iterations.

Component Transformation Matrix

Component	1	2
1	.742	.670
2	670	.742

Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.

Communality (which is the opposite of uniqueness) is the proportion of variance of the variable (i.e., read) that is accounted for by all of the factors taken together, and a very low communality can indicate that a variable may not belong with any of the factors. The scree plot may be useful in determining how many factors to retain. From the component matrix table, we can see that all five of the test scores load
